

This would be my entity-relationship diagram. The core table of the database is Bootcamps, which has the primary key bootcamp_id. This key is used as a foreign key in the teacher_bootcamp table. In that same table, there's also teacher_id, which is also a foreign key. This intermediate table is necessary because the relationship between teachers and bootcamps is many-to-many — a teacher can teach in several bootcamps, and each bootcamp can have multiple teachers. The relationship continues with the Teachers table, where teacher_id is the primary key, as previously mentioned in the teacher_bootcamp table.

On the other hand, we have a similar case with the registro (enrollment) table, which connects the bootcamps table with the students table. Since each student can enroll in multiple bootcamps, and each bootcamp can have multiple students, this intermediate table allows that relationship. The registro table connects with bootcamps via bootcamp_id, and with students via student_id. The table also has its own primary key: registro_id. The next table, students, links back to registro through its primary key student_id, which acts as a foreign key in the registro table.

The last relationship we find is between bootcamps and the intermediate table troncal_subjects. This table has troncal_subjects_id as its primary key, and uses bootcamp_id (from bootcamps) and subject_id (from subjects) as foreign keys. This intermediate table is used because core subjects can appear in multiple bootcamps, and bootcamps can include multiple core subjects. The troncal_subjects table connects with the subjects table, which uses subject_id as its primary key.
